

## *Supplementary Material A: Sample Descriptions based on Viewing Time*

### **Study 1**

With 83% reporting to have achieved the Abitur, VT-inferred teleiophilic men were more likely to be highly educated than VT-inferred pedohebephilic men, who had Abitur in 61% of cases ( $\chi^2 = 9.76$ ,  $df = 1$ ,  $p = .002$ ,  $\phi = .25$ ). In the pedohebephilic group, 11.9%, 0.0%, and 23.9% reported prior convictions for child sexual abuse, rape, and child pornography offenses, respectively. In the teleiophilic group, 4.4% reported prior convictions for child pornography offenses, but none reported convictions for child sexual abuse or rape. Pedo-SO/+SO were older than Tel-SO, and Pedo-SO were younger than Pedo+SO (see Table S1 and S2 in Supplement B). There were no differences in educational level between Pedo-SO and Pedo+SO ( $\chi^2 = 2.37$ ,  $df = 1$ ,  $\phi = -.19$ ,  $p = .123$ ), but between Pedo-SO/+SO and Tel-SO ( $\chi^2 = 9.90$ ,  $df = 1$ ,  $\phi = .25$ ,  $p = .002$ )

### **Study 2**

We found high education levels in the three VT-based groups (42%, 60%, and 59% with an associate degree, BA. degree, or higher in VT-based pedophilic, hebephilic, and teleiophilic group, respectively). Among the three groups, 18%, 14%, and 4% reported convictions for sexual offenses (for pedophilic, hebephilic, and teleiophilic men, respectively). Differences between Pedo-SO, Pedo+SO, and Tel-SO were not significant regarding educational level ( $\chi^2 = 4.26$ ,  $df = 2$ ,  $\phi = .01$ ,  $p = .118$ ) or age (see Table S3).

*Supplementary Material C: Control analyses based on viewing time.*

**Study 1.** We found no links between age and height for VT-based Pedo+SO ( $r = -.40$ ,  $p = .076$ , 95%  $CI = [-.71, .04]$ ) and Tel-SO ( $r = -.07$ ,  $p = .549$ , 95%  $CI = [-.27, .15]$ ), but height was significantly negatively associated with age for Pedo-SO ( $r = -.36$ ,  $p = .014$ , 95%  $CI = [-.59, -.08]$ ). For head injuries before age 13, we did not find significant links to age for any of the three VT-based groups (Pedo-SO:  $r = .17$ , 95%  $CI = [-.01, .41]$ , Pedo+SO:  $r = .31$ , 95%  $CI = [-.21, .65]$ , Tel-SO:  $r = .44$ , 95%  $CI = [-.11, .24]$ ). We also could not detect links between head injuries after age 13 and age (Pedo-SO:  $r = -.001$ , 95%  $CI = [-.25, .32]$ , Pedo+SO:  $r = .26$ , 95%  $CI = [-.11, .56]$ , Tel-SO:  $r = -.06$ , 95%  $CI = [-.23, .17]$ ). The associated confidence intervals for the head injury measures are based on 1,000 bootstrap samples. Hence, only 1/9 correlations reached significance.

**Study 2.** We detected no links between height (all  $p < .150$ ), IQ (all  $p < .475$ ) or head injuries before age 13 (no 95%  $CI$  based on 1,000 bootstrap samples containing 0) and age for any of the three VT-based groups. For Pedo+SO, we detected a link between age and head injuries after age 13 ( $r = -.25$ , 95%  $CI$  based on 1,000 bootstrap samples =  $[-.46, -.01]$ , note that the associated confidence intervals are). Hence, only 1/12 correlations reached significance.
